What is Redbelly?

A layer 1 blockchain built for tokenising real world assets, where every participant is verified.

Redbelly Network
Built to be FAST

F
Finality
Final in seconds. No forks.

A
Accountability
Every participant is known.

S
Security
Consensus proven correct.

T
Throughput
97,500 transactions a second shown.

Made for real assets
Issue and manage regulated assets as tokens.

Born from research
Consensus developed with the University of Sydney and CSIRO.

Speaks Ethereum
Runs Solidity smart contracts on an EVM.

REDBELLY

Why tokenise real world assets?

A token records ownership, with the rules written in. The asset and its legal rights stay the same.

	TRADITIONAL		TOKENISED
Settlement	Usually T+2 in Australia	→	Compliant transfers settle in seconds
Transfers	Registry business hours	→	Can be transferred at any time
Access	Often large minimums	→	Can be split into smaller units
Compliance	Checked by hand per transfer	→	Breaking a rule blocks the transfer

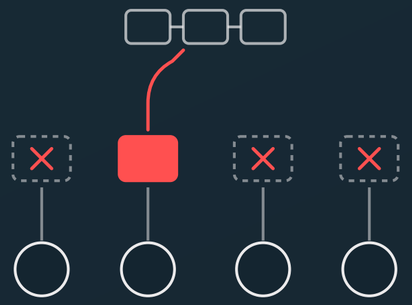

Per Tokeniser, for Australian funds and companies on Redbelly. Investor eligibility rules still apply.

REDBELLY

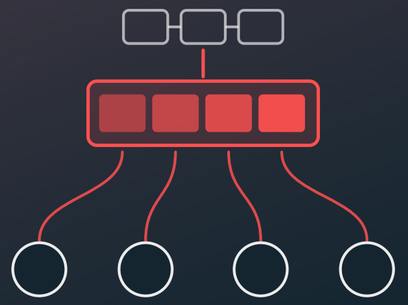

DBFT consensus

Democratic Byzantine Fault Tolerance is how Redbelly's nodes agree. There is no leader. Nodes build every block together.

Most blockchains compete

One block wins. The rest is wasted work.

Redbelly nodes combine

Every node's transactions join one superblock.

No leader

Every node plays a similar role. No single point of failure.

Final once confirmed

No forks. Cannot be reversed.

Proven correct

Formally verified. Works while under a third of nodes are faulty.

REDBELLY

What is Receptor?

Redbelly's own identity and verifiable credential protocol. It checks who can use the network and each product.

You
Credentials in a wallet

→

Network access
Accredited issuer's credential

→

Redbelly
Every participant verified

→

Product rules
Such as wholesale investor

→

Product
Only eligible users get in

MODULES **Issuer** **Holder** **Verifier** Built on the W3C standard

Accredited issuers
Only they grant network access.

Rules per product
Apps set them. Users prove them.

Two ways to prove
Zero knowledge on-chain, or some fields off-chain.

Sources: Redbelly docs: Receptor · Last verified 31 Oct 2026

REDBELLY

Verifiable credentials

A digital proof about you, signed by a trusted issuer and kept in your own wallet.

The verifier trusts the issuer

Issuer
Checks you, then signs

→

You
Keep it, share proof

→

Verifier
Checks the signature

AML/CTF CREDENTIAL	
Status	Passed
Issued to	Your wallet
Signed by issuer	

Reuse it
Less repeat KYC onboarding.

Keep it
Your data stays with you.

Trust it
Forgeries fail the check.

REDBELLY

Zero knowledge proofs

Prove something is true without revealing the data behind it.

1 THE QUESTION

Is this user over 18?

→

2 YOUR WALLET

Builds a proof. Birth date stays hidden.

Birth date ■■■■

→

3 SMART CONTRACT

Checks the proof on Redbelly

→

4 THE ANSWER

True or false. No personal data on-chain.

True

Selective Disclosure
Shows only the fields asked for. Off-chain.

Proof by Query (zero knowledge)
Shares only the proof. No data.

What is Tokeniser?

A Redbelly Network project that lets funds and companies issue and run tokenised assets, without a technology project.

1. **Set up**
   Define the asset and its rules
2. **Onboard**
   Investors verify identity and status
3. **Issue**
   Tokens go to verified wallets
4. **Transfer**
   Checked, then settled in seconds
5. **Pay and report**
   Payouts and records automated

A$2B+
transactions processed

160+
companies and funds

A$1.2B
equity and funds issued

Figures published by Tokeniser, 31 Oct 2026

REDBELLY

Compliance aware assets

The rules travel with the asset. Every transfer is checked against them before it can settle.

Tokenised asset

RULES BUILT IN

- Identity verified (KYC, AML)
- Eligible investor type
- Lock-up periods
- Foreign ownership caps

TRANSFER ATTEMPTS

Verified, eligible wallet
Settles

Unverified wallet
Rejected before it settles

Programmed in

Issuers write the rules into the asset.

Checked every time

Failed checks stop the trade. All are logged.

Inherited

Apps using the asset inherit its rules.

Sources: Redbelly whitepaper, website, Tokeniser · Last verified 31 Oct 2026

REDBELLY

Identity and accountability

Every network participant is identity-verified. Nodes that try to make honest nodes disagree leave signed evidence.

PARTICIPANTS	People, businesses and AI agents	Verified by accredited issuers	Transactions can be tied to a responsible party
NODES	Faulty nodes try to cause disagreement	Their signed traces become proof of fraud	Enough proof removes them from consensus

Designed to tolerate attackers that control more than half the system.

Zero knowledge proofs can prove a fact without revealing the data.

How the DAO decides

Only verified wallets can vote on the DAO voting platform. Every ballot is signed and public.

1 PROPOSE

Signed, no gas. Locked once open.

→

2 VOTE

Only wallets with a Receptor credential.

→

3 COUNT

Method, power and quorum set per proposal.

→

4 RECORD

Signed ballots, receipts on IPFS.

Identity quorum

A minimum number of different verified voters. One large holder cannot meet it alone.

IN FORCE NOW

- New treasury-funded work paused until a future vote.
- High Council: 3 seats, elected July 2026.
- 5 pods: Marketing, Builder/Develop, Researcher, Community, Partnerships.

Project Acacia

The Reserve Bank of Australia's real money pilot of tokenised assets and digital money. Redbelly was one of the networks it ran on.

2024
Phase 1 maps settlement models

Jul 2025
Phase 2 starts. Redbelly selected.

Feb 2026
Live pilots with real money end

May 2026
RBA publishes its Final Report

3
networks got the RBA's pilot wholesale CBDC. Redbelly was the only public one.

5
of 20 completed use cases ran on Redbelly mainnet.

Under 4 min
to issue and resell a tokenised bond. Normally up to 4 days.

Wholesale CBDC: central bank digital money used between financial institutions.
