What is Redbelly?

A layer 1 blockchain built for tokenising real world assets, where every participant is verified.

F
Finality
Final within seconds. No forks.

A
Accountability
Every participant is known.

S
Security
Consensus proven correct.

T
Throughput
97,500 transactions a second shown.

Made for real assets
Issue, manage and distribute regulated financial assets as tokens.

Born from research
Consensus developed with the University of Sydney and CSIRO.

Speaks Ethereum
A scalable EVM runs Solidity smart contracts.

Why tokenise real world assets?

Tokenising records ownership as a digital token, with the asset's rules built in. What you own stays the same. How it moves changes.

	TRADITIONAL		TOKENISED
Settlement	Takes days (T+2)	→	Seconds, in one transaction
Trading hours	Registry business hours	→	Any time, 24/7
Access	Large minimum investments	→	Smaller fractional units
Compliance	Manual checks	→	Checked on every transfer

REDBELLY

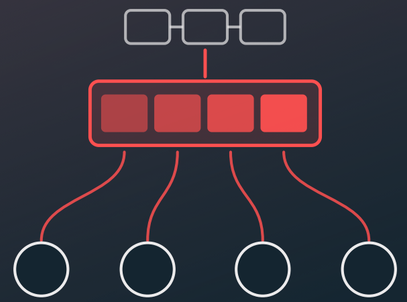

DBFT consensus

Democratic Byzantine Fault Tolerance is how Redbelly's nodes agree. There is no leader. Nodes build every block together.

Most blockchains compete

One block wins. The rest is wasted work.

Redbelly nodes combine

Every node's transactions join one superblock.

No leader

Every node plays a similar role. No single point of failure.

Final once confirmed

No forks. A confirmed transaction cannot be reversed.

Proven correct

Formally verified. Works while under a third of nodes are faulty.

REDBELLY

What is Receptor?

Receptor is Redbelly's own digital identity and verifiable credential protocol. It checks who can use the network and who can access each product.

You
Hold credentials in a wallet

→

Network access
Needs an accredited issuer's credential

→

Redbelly
Every participant verified

→

Product rules
Such as: wholesale investor

→

Product
Only eligible users get in

MODULES **Issuer** **Holder** **Verifier** Built on the W3C standard

Accredited issuers
Only accredited issuers can grant network access.

Rules per product
Apps set criteria. Users prove they meet them.

Two ways to prove
On-chain with zero knowledge, or off-chain by sharing only some fields.

Sources: docs.redbelly.network/pages/receptor · Last verified 26 Oct 2026

REDBELLY

Verifiable credentials

A digital proof about you, such as a passed AML check. A trusted issuer signs it and you keep it in your own wallet.

The verifier trusts the issuer

Issuer
Checks you once, then signs

→

You
Keep it. Share proof when asked.

→

Verifier
Checks the issuer's signature

AML/CTF CREDENTIAL	
Status	Passed
Issued to	Your wallet
Signed by issuer	

Reuse it
Reusable identity and KYC credentials cut repeat onboarding.

Keep it
Your data stays with you, not in every company's database.

Trust it
Checked against the issuer's public key, so forgeries fail.

Zero knowledge proofs

Prove something is true without revealing the data behind it.

1 THE QUESTION
Is this user over 18?

→

2 YOUR WALLET
Builds a proof. Birth date stays hidden.
Birth date ■■■

→

3 SMART CONTRACT
Checks the proof on Redbelly

→

4 THE ANSWER
Just true or false. No personal data on-chain.
True

Selective Disclosure
Reveals only the fields asked for. Off-chain.

Zero knowledge (Proof by Query)
Shares only the proof. No data at all.

Sources: docs.redbelly.network: Selective Disclosure vs Proof by Query · Last verified 26 Oct 2026

What is Tokeniser?

A Redbelly Network project that lets funds and companies issue and run tokenised assets on Redbelly, without a technology project.

1. **Set up**
   Define the asset and its rules
2. **Onboard**
   Investors verify identity and status
3. **Issue**
   Tokens go to verified wallets
4. **Transfer**
   Checked, then settled in seconds
5. **Pay and report**
   Payouts and records automated

A$2B+
transactions processed

160+
companies and funds

A$1.2B
equity and funds issued

Figures published by Tokeniser, 26 Oct 2026

REDBELLY

Compliance aware assets

The rules travel with the asset. Every transfer is checked against them before it can settle.

Tokenised asset

RULES BUILT IN

- Identity verified (KYC, AML)
- Eligible investor type
- Transfer limits, like lock-ups
- Foreign ownership caps

TRANSFER ATTEMPTS

Verified, eligible wallet
Settles

Unverified wallet
Rejected before it settles

Programmed in

Issuers write eligibility rules into the asset itself.

Checked every time

Transfers that break a rule fail. Every check is logged.

Inherited

Apps using the asset on Redbelly inherit its rules.

REDBELLY

Identity and accountability

On Redbelly, every participant is known and cheating nodes can be caught with proof. The whitepaper calls this accountable blockspace.

PEOPLE	People, businesses and AI agents	→ Verified by accredited issuers	→ Every transaction traces to someone responsible
NODES	A node tries to cheat	→ Its signed messages become proof of fraud	→ Proven faulty nodes are removed

This works even if a majority of nodes collude.

Identities are verified. Zero knowledge proofs keep personal data private.

How the DAO decides

Redbelly Community DAO members vote on the DAO voting platform. Only verified wallets can vote, and every ballot is signed and public.

1 PROPOSE

Signed, no gas. Locked once voting opens.

→

2 VOTE

Only wallets with a Receptor credential.

→

3 COUNT

Each proposal sets its method, power and quorum.

→

4 RECORD

Signed ballots, receipts on IPFS. Anyone can check.

Identity quorum

A minimum number of different verified voters. One large holder cannot meet it alone.

IN FORCE NOW

- New treasury-funded work is paused until a future vote.
- High Council: 3 seats, elected July 2026.
- 5 pods: Marketing, Builder/Develop, Researcher, Community, Partnerships.

Project Acacia

The Reserve Bank of Australia's real money pilot of tokenised assets and digital money. Redbelly was one of the networks it ran on.

2024
Phase 1 maps settlement models

Jul 2025
Phase 2 starts. Redbelly selected.

Jul 2025 to Feb 2026
Live pilots with real money and assets

May 2026
RBA publishes its Final Report

3
networks received the RBA's pilot wholesale CBDC. Redbelly was the only public one.

5
of 20 completed use cases ran on Redbelly mainnet.

Under 4 min
to issue and resell a tokenised bond on Redbelly. Normally up to 4 days.

Wholesale CBDC: central bank digital money used between financial institutions.
